

## Assignment-4.2(10I7)

Name: Alli Harika

Ht.no: 2303A510I7

Batch. No: 21

---

### Question 1: Zero-Shot Prompting (Prime Number Check)

#### Task

Write a zero-shot prompt to generate a Python function that checks whether a given number is prime.

#### Prompt used:

Write a Python function that checks whether a given number is prime or not.

#### Code:

```
#Write a Python function that checks whether a given number is prime or
def is_prime(n):
    """Return True if n is a prime number, else False."""
    if n <= 1:
        return False
    if n <= 3:
        return True
    if n % 2 == 0 or n % 3 == 0:
        return False
    i = 5
    while i * i <= n:
        if n % i == 0 or n % (i + 2) == 0:
            return False
        i += 6
    return True
# Example usage:
number = int(input("Enter a number to check if it is prime: "))
if is_prime(number):
    print(f"{number} is a prime number.")
else:
    print(f"{number} is not a prime number.")
```

**Output:**

```
C:\Users\dell\OneDrive\Desktop\AI\20-01-2026>
Enter a number to check if it is prime: 29
29 is a prime number.
PS C:\Users\dell\OneDrive\Desktop\AI>
```

**Justification:**

This zero-shot prompt provided only an instruction without examples. The AI generated a basic and logically correct prime-checking function. However, the solution is not optimized because it checks divisibility up to n-1. This demonstrates that zero-shot prompting works but may lack efficiency and edge-case optimization.

**Question 2: One-Shot Prompting (Sum of List Elements)****Task:**

Provide one example to guide AI in generating a function to sum elements of a list.

**Prompt Used:**

Write a Python function to calculate the sum of elements in a list.

**Example:**

Input: [1, 2, 3, 4]

Output: 10

**Code:**

```
#Write a Python function to calculate the sum of elements in a list.  
#Example:  
#Input: [1, 2, 3, 4]  
#Output: 10  
def sum_list(numbers):  
    total = 0  
    for num in numbers:  
        total += num  
    return total  
  
lst = [1, 2, 3, 4]  
print("Sum:", sum_list(lst))
```

Output:

```
132-64\debugpy\launcher 50582 -- C:\Users\dell\OneDrive\Desktop\AI\20-01-2026.py'  
Sum: 10  
PS C:\Users\dell\OneDrive\Desktop\AI> []
```

### Justification:

The one-shot example clearly guided the AI to understand:

- Input format (list)
- Expected output (sum)

Compared to zero-shot prompting, one-shot prompting improves clarity and correctness by giving a reference pattern.

### Question 3: Few-Shot Prompting (Extract Digits from Alphanumeric String)

#### Task

Use 2–3 examples to generate a function that extracts digits from an alphanumeric string.

#### Prompt Used

Write a Python function that extracts digits from an alphanumeric string.

Examples:

Input: "a1b2c3" → Output: "123"

Input: "abc123xyz" → Output: "123"

Input: "9a8b7" → Output: "987"

Code:

```
#Write a Python function that extracts digits from an alphanumeric string
#Examples:
#Input: "a1b2c3" → Output: "123"
#Input: "abc123xyz" → Output: "123"
#Input: "9a8b7" → Output: "987"

def extract_digits(s):
    digits = ""
    for char in s:
        if char.isdigit():
            digits += char
    return digits

# Example usage:
input_str = input("Enter an alphanumeric string: ")
result = extract_digits(input_str)
print("Extracted digits:", result)
```

Output:

```
've\Desktop\AI\20-01-2026.py'
Enter an alphanumeric string: a1b2c3
Extracted digits: 123
PS C:\Users\dell\OneDrive\Desktop\AI> █
```

### Justification:

Few-shot prompting helped the AI:

- Identify the pattern across multiple examples
- Use `.isdigit()` effectively
- Produce accurate and consistent output

This shows few-shot prompting significantly improves reliability and pattern recognition.

### Question 4: Zero-Shot vs Few-Shot Prompting (Vowel Count Comparison)

## **Zero-Shot Prompt:**

Write a Python function to count the number of vowels in a string.

Code:

```
#Write a Python function to count the number of vowels in a string.
def count_vowels(s):
    vowels = "aeiouAEIOU"
    count = 0
    for char in s:
        if char in vowels:
            count += 1
    return count
# Example usage:
input_str = input("Enter a string: ")
vowel_count = count_vowels(input_str)
print("Number of vowels:", vowel_count)
```

Output:

```
32-x64\bundled\libs\debugpy\launcher'
ve\Desktop\AI\20-01-2026.py'
nter a string: hello
umber of vowels: 2
S C:\Users\dell\OneDrive\Desktop\AI> █
```

## **Few-Shot Prompt:**

Write a Python function to count vowels in a string.

Examples:

Input: "hello" → Output: 2

Input: "education" → Output: 5

## **Few-Shot Code:**

```

#Few-Shot Code Write a Python function to count vowels in a string.
#Examples:
#Input: "hello" → Output: 2
#Input: "education" → Output: 5
def count_vowels(s):
    vowels = "aeiouAEIOU"
    return sum(1 for ch in s if ch in vowels)
# Example usage:
input_str = input("Enter a string: ")
vowel_count = count_vowels(input_str)
print("Number of vowels:", vowel_count)

```

## Output:

```

n32-x64\bundled\libs\debugpy\launcher' '4930
ive\Desktop\AI\20-01-2026.py'
Enter a string: hello
Number of vowels: 2
PS C:\Users\dell\OneDrive\Desktop\AI>

```

## Comparison Output

Prompt Type	Accuracy	Case Handling	Efficiency
Zero-shot	Medium	No	Low
Few-shot	High	Yes	High

## Justification:

Few-shot prompting helped the AI:

- Handle uppercase vowels
- Write more optimized and concise code
- Improve overall logic quality

This clearly proves examples significantly enhance AI understanding

## Question 5: Few-Shot Prompting (Minimum of Three Numbers)

## Task

Generate a function to find the minimum of three numbers **without using min()**.

### Prompt Used:

Write a Python function to find the minimum of three numbers without using min().

Examples:

Input: 3, 7, 5 → Output: 3

Input: 10, 2, 8 → Output: 2

Input: -1, -5, 0 → Output: -5

Code:

```
#Write a Python function to find the minimum of three numbers without u
#Examples:
#Input: 3, 7, 5 → Output: 3
#Input: 10, 2, 8 → Output: 2
#Input: -1, -5, 0 → Output: -5
def min_of_three(a, b, c):
    if a <= b and a <= c:
        return a
    elif b <= a and b <= c:
        return b
    else:
        return c
# Example usage:
num1 = float(input("Enter first number: "))
num2 = float(input("Enter second number: "))
num3 = float(input("Enter third number: "))
minimum = min_of_three(num1, num2, num3)
print("The minimum of the three numbers is:", minimum)
```

Output:

```
C:\Users\dell\OneDrive\Desktop\AI> python C:\Users\dell\OneDrive\Desktop\AI\20-01-2026.py
Enter first number: 3
Enter second number: 7
Enter second number: 7
Enter third number: 5
The minimum of the three numbers is: 3.0
PS C:\Users\dell\OneDrive\Desktop\AI>
```

## Justification

Few-shot prompting guided the AI to:

- Handle negative numbers
- Use logical comparisons correctly
- Avoid built-in functions as instructed

This resulted in **accurate and well-structured logic**.

## Conclusion

- **Zero-shot prompting** is useful for simple tasks but may lack optimization.
- **One-shot prompting** improves clarity and correctness.
- **Few-shot prompting** delivers the most accurate, efficient, and reliable results.
- Providing examples greatly enhances AI code quality and understanding.
